

Q.2 a. If $y = X^{X^{X^{\dots \dots \infty}}}$, then prove that $X \frac{dy}{dX} = \frac{y^2}{(1 - y \log_e X)}$

Ans. we have $y = X^{X^{X^{\dots \dots \infty}}} = X^y$ [$\because X^{X^{X^{\dots \dots \infty}}} = y$]

by taking \log of both sides, we get

$$\log y = y \log x$$

differentiating w.r.t. x

$$\frac{1}{y} \frac{dy}{dx} = \frac{y}{x} + (\log x) \frac{dy}{dx}$$

$$\frac{dy}{dx} \left(\frac{1}{y} - \log x \right) = \frac{y}{x}$$

$$\Rightarrow \frac{dy}{dx} = \frac{y^2}{1 - y \log x}$$

Hence Proved

b. Find the equation of the tangent to the curve $x^2 + 2y = 8$ which is perpendicular to the line $x - 2y + 1 = 0$.

Ans. The given curve is $x^2 + 2y = 8$ _____ (i)

Differentiating w.r.t. 'x' we get

$$2x + 2 \frac{dy}{dx} = 0 \Rightarrow \frac{dy}{dx} = -x$$

and the given line is $x - 2y + 1 = 0$

Differentiating w.r.t. 'x' we get

$$1 - 2 \frac{dy}{dx} = 0 \Rightarrow \frac{dy}{dx} = \frac{1}{2}$$

Since the tangent is perpendicular to the line therefore, (slope of tangent) (slope of line) = -1

$$\Rightarrow (-x) \left(\frac{1}{2} \right) = -1 \Rightarrow x = 2$$

Now, we have to find y co-ordinate when $x = 2$ on putting $x = 2$ in (i), we get

$$(2)^2 + 2y = 8 \Rightarrow 2y = 8 - 4 = 4 \Rightarrow y = 2$$

\therefore Equation of tangent to (i) at the point (2, 2) is,

$$y - 2 = -2(x - 2)$$

$$\Rightarrow y - 2 = -2x + 4$$

$$\Rightarrow 2x + y = 6$$

Q.3 a. Evaluate $\int e^{-x} \cdot \cos x dx$

Ans. Let $I = \int e^{-x} \cdot \cos x dx$, then

$$\begin{aligned} & \text{I} \quad \text{II} \\ &= e^{-x} \sin x - \int -e^{-x} \cdot \sin x dx \\ &= e^{-x} \sin x + \int e^{-x} \cdot \sin x dx \\ & \quad \text{I} \quad \text{II} \\ &= e^{-x} \sin x + e^{-x}(-\cos x) - \int (-e^{-x})(-\cos x) dx \\ &= e^{-x} \sin x - e^{-x} \cos x - \int e^{-x} \cos x dx \\ &\text{or } I = e^{-x} \sin x - e^{-x} \cos x - I \\ &\text{or } 2I = e^{-x} (\sin x - \cos x) \\ &\text{or } I = \frac{e^{-x}}{2} (\sin x - \cos x) \end{aligned}$$

b. Evaluate $\int_1^2 \frac{1}{x(1+x^2)} dx$

Ans. Let $\frac{1}{x(1+x^2)} = \frac{A}{x} + \frac{Bx+C}{1+x^2}$, then

$$1 = A(1+x^2) + (Bx+C)x \quad \text{(i)}$$

Putting $x = 0$ in (i), we get $A = 1$. Comparing the coefficients of x^2 and x , we get,

$$A + B = 0 \text{ and } C = 0 \Rightarrow B = -1 \text{ and } C = 0 \quad [\because A = 1]$$

$$\therefore \frac{1}{x(1+x^2)} = \frac{1}{x} - \frac{x}{1+x^2}$$

$$\text{So, } \int_1^2 \frac{1}{x(1+x^2)} dx = \int_1^2 \frac{1}{x} dx - \frac{1}{2} \int_1^2 \frac{2x}{1+x^2} dx$$

$$= [\log x]_1^2 - \frac{1}{2} [\log(1+x^2)]_1^2$$

$$= (\log 2 - \log 1) - \frac{1}{2} [\log 5 - \log 2]$$

$$= \log 2 - \frac{1}{2} \log 5 + \frac{1}{2} \log 2$$

$$= \frac{3}{2} \log 2 - \frac{1}{2} \log 5$$

Q.4 a. Find the matrix A satisfying the equation $\begin{bmatrix} 2 & 1 \\ 3 & 3 \end{bmatrix} A \begin{bmatrix} 5 & 3 \\ 3 & 2 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

Ans. Let $|B| = \begin{vmatrix} 2 & 1 \\ 3 & 3 \end{vmatrix}$ and $|C| = \begin{vmatrix} 5 & 3 \\ 3 & 2 \end{vmatrix}$, then

$$|B| = \begin{vmatrix} 2 & 1 \\ 3 & 3 \end{vmatrix} = 6 - 3 = 3 \neq 0 \text{ and}$$

$$|C| = \begin{vmatrix} 5 & 3 \\ 3 & 2 \end{vmatrix} = 10 - 9 = 1 \neq 0$$

So, B and C are invertible matrices. The given matrix equation is $BAC = I$

on pre-multiplying by B^{-1} and post multiplying by C^{-1} , we get,

$$\Rightarrow B^{-1} (BAC) C^{-1} = B^{-1} I C^{-1}$$

$$\Rightarrow (B^{-1}B) A (C C^{-1}) = B^{-1} \cdot C^{-1}$$

$$\Rightarrow I A I = B^{-1} \cdot C^{-1}$$

$$\Rightarrow A = B^{-1} \cdot C^{-1} \quad \text{----- (i)}$$

$$\text{Matrix of co-factors of B} = \begin{bmatrix} 3 & -3 \\ -1 & 2 \end{bmatrix}$$

$$\text{Adjoint B} = \begin{bmatrix} 3 & -1 \\ -3 & 2 \end{bmatrix}$$

$$B^{-1} = \frac{1}{|B|} \text{Adj B} = \frac{1}{3} \begin{bmatrix} 3 & -1 \\ -3 & 2 \end{bmatrix} \quad \text{----- (ii)}$$

$$\text{Matrix of co-factors of C} = \begin{bmatrix} 2 & -3 \\ -3 & 5 \end{bmatrix}$$

$$\text{Adjoint C} = \begin{bmatrix} 2 & -3 \\ -3 & 5 \end{bmatrix}$$

$$C^{-1} = \frac{1}{|C|} \text{Adj C} = \begin{bmatrix} 2 & -3 \\ -3 & 5 \end{bmatrix} \quad \text{----- (iii)}$$

on putting the value of B^{-1} from (ii) and C^{-1} from (iii) in (i), we get

$$\begin{aligned} \therefore A = B^{-1} \cdot C^{-1} &= \frac{1}{3} \begin{bmatrix} 3 & -1 \\ -3 & 2 \end{bmatrix} \begin{bmatrix} 2 & -3 \\ -3 & 5 \end{bmatrix} \\ &= \frac{1}{3} \begin{bmatrix} 6+3 & -9+5 \\ -6-6 & 9+10 \end{bmatrix} = \frac{1}{3} \begin{bmatrix} 9 & -14 \\ -12 & 19 \end{bmatrix} \\ &= \begin{bmatrix} 3 & -14/3 \\ -4 & 19/3 \end{bmatrix} \end{aligned}$$

b. Solve the following set of equations by using Cramer's rule

$$2x - y + 3z = 9, x + y + z = 6, x - y + z = 2$$

Ans. Let $\Delta = \begin{vmatrix} 2 & -1 & 3 \\ 1 & 1 & 1 \\ 1 & -1 & 1 \end{vmatrix} = -2$

$$\Delta x = \begin{vmatrix} 9 & -1 & 3 \\ 6 & 1 & 1 \\ 2 & -1 & 1 \end{vmatrix} = -2$$

$$\Delta y = \begin{vmatrix} 2 & 9 & 3 \\ 1 & 6 & 1 \\ 1 & 2 & 1 \end{vmatrix} = -4$$

$$\Delta z = \begin{vmatrix} 2 & -1 & 9 \\ 1 & 1 & 6 \\ 1 & -1 & 2 \end{vmatrix} = -6$$

$$\text{Now, } x = \frac{\Delta x}{\Delta} = \frac{-2}{-2} = 1$$

$$y = \frac{\Delta y}{\Delta} = \frac{-4}{-2} = 2$$

$$z = \frac{-6}{-2} = 3$$

$$x = 1, y = 2, z = 3$$

Q.5 a. Solve $x^2 dy + y(x + y) dx = 0$

Ans. The given equation is $\frac{dy}{dx} + \frac{y(x + y)}{x^2} = 0$ _____ (i)

which is a homogeneous differential equation of first order, putting $y = v x$

and $\frac{dy}{dx} = v + x \frac{dv}{dx}$, equation (i) yields

$$v + x \frac{dv}{dx} + \frac{vx(x + vx)}{x^2} = 0$$

$$\text{or } x \frac{dv}{dx} + v^2 + 2v = 0$$

$$\text{or } \frac{dv}{v^2 + 2v} + \frac{dx}{x} = 0$$

$$\frac{1}{2} \left(\frac{1}{v} + \frac{1}{v+2} \right) dv + \frac{dx}{x} = 0$$

on integrating the required solution is

$$\frac{1}{2} [\log v - \log(v+2)] + \log x = \log c$$

$$\log \left(x \sqrt{\frac{v}{v+2}} \right) = \log c$$

$$\text{or } x \sqrt{\frac{y/x}{y/x+2}} = c, \text{ as } v = \frac{y}{x}$$

$$\text{or } x \sqrt{\frac{y}{y+2x}} = c$$

$$x^2 y = a(y + 2x) \text{ where } c^2 = a$$

b. Solve $(1 + y^2)dx + xdy = \tan^{-1} y dy$

Ans. $(1+y^2)dx = (\tan^{-1}y - x) dy$

$$\Rightarrow (1+y^2) \frac{dx}{dy} = \tan^{-1} y - x$$

$$\Rightarrow \frac{dx}{dy} = \frac{\tan^{-1} y}{1+y^2} - \frac{x}{1+y^2}$$

$$\Rightarrow \frac{dx}{dy} + \frac{x}{1+y^2} = \frac{\tan^{-1} y}{1+y^2}$$

$$\begin{aligned} \Rightarrow \text{I. F.} &= e^{\int \frac{1dx}{1+y^2}} \\ &= e^{\tan^{-1} y} \end{aligned}$$

So solution of the given differential equation is,

$$= x e^{\tan^{-1} y} = \int \frac{\tan^{-1} y}{1+y^2} \cdot e^{\tan^{-1} y} \cdot dy + c$$

$$\Rightarrow x e^{\tan^{-1} y} = \int \frac{\tan^{-1} y \cdot e^{\tan^{-1} y} \cdot dy}{1+y^2} + c$$

Put $\tan^{-1} y = t$

$$\Rightarrow \frac{1}{1+y^2} dy = dt$$

$$\Rightarrow x e^{\tan^{-1} y} = \int t e^t dt + c$$

$$\Rightarrow x e^{\tan^{-1} y} = t e^t - \int e^t dt + c$$

$$\Rightarrow x e^{\tan^{-1} y} = t e^t - e^t + c$$

$$\Rightarrow x e^{\tan^{-1} y} = e^t (t - 1) + c$$

$$\Rightarrow x e^{\tan^{-1} y} = e^{\tan^{-1} y} (\tan^{-1} y + 1) + c$$

$$\Rightarrow (\tan^{-1} y - 1) + c e^{\tan^{-1} y} = x$$

Q.6 a. Prove that the coefficient of x^r in the expansion of $(1-4x)^{-1/2}$ is $\frac{(2r)!}{(r!)^2}$

Ans. We know that the general term of the expansion

$$(1+x)^n \text{ is } T_{r+1} = \frac{n(n-1)(n-2)\dots(n+1-r) \cdot x^r}{r!}$$

Putting $n = -\frac{1}{2}$ and $-4x$ for x , we get

$$T_{r+1} = \frac{\left(-\frac{1}{2}\right)\left(-\frac{3}{2}\right)\left(-\frac{5}{2}\right)\dots\left[-\left(\frac{2r-1}{2}\right)\right]}{r!} (-1)^r \cdot (2^2)^r \cdot x^r$$

$$= (-1)^r (-1)^r \frac{1.3.5.7.....(2r-1)}{2^r \times r!} \cdot 2^{2r} \cdot x^r$$

$$= \frac{1.3.5.7.....(2r-1)}{r!} 2^r \cdot x^r$$

Multiplying and dividing by 2.4.6...2r, we have

$$= \frac{1.2.3.4.....(2r-1)^{2r}}{[2.4.6.8...2r]r!} 2^r \cdot x^r = \frac{2r!}{2^r (1.2.3..r)r!} 2^r \cdot x^r$$

$$= \frac{2r!}{r!r!} x^r = \frac{2r!}{(r!)^2} x^r$$

Hence, the coefficient of x^r is $\frac{2r!}{(r!)^2}$ Proved

b. Find three number in A.P. whose sum is 21 and their product is 315.

Ans. Let three numbers is A.P. be,
 $a - d, a, a + d$ _____ (i)

Their sum $a - d + a + a + d = 21$

$$\therefore 3a = 21 \Rightarrow a = 7$$

Now product of 3 numbers = $(a - d) a (a + d)$

$$\therefore (a - d) \cdot a (a + d) = 315$$

Putting the value of a, we get

$$(7-d) 7 (7 + d) = 315$$

$$\Rightarrow (49 - d^2) = \frac{315}{7} = 45$$

$$\Rightarrow d^2 = 49 - 45 = 4$$

$$\Rightarrow d = \pm 2$$

Case I- When $a = 7, d = 2$ putting in (i)

\therefore Numbers are $7-2, 7, 7+2$ i.e. 5, 7, 9

Case II When $a = 7, d = -2$ putting in (i)

\therefore Numbers $7+2, 7, 7-2$ is 9, 7, 5

\therefore Required three numbers are 5, 7, 9, or 9, 7, 5

- Q.7 a.** If A, B, C are the angles of a triangle, then prove that, $\tan 2A + \tan 2B + \tan 2C = \tan 2A \cdot \tan 2B \cdot \tan 2C$

Given that $A + B + C = \pi = 180^\circ$

then $2A + 2B + 2C = 360^\circ$

or $2A + 2B = 360^\circ - 2C$

Taking tangent of both sides

$\tan(2A + 2B) = \tan(360^\circ - 2C)$

$$\frac{\tan 2A + \tan 2B}{1 - \tan 2A \cdot \tan 2B} = -\tan 2C$$

Cross-multiplying

$$\therefore \tan 2A + \tan 2B = -\tan 2C + \tan 2A \cdot \tan 2B \cdot \tan 2C$$

Transposing,

$$\tan 2A + \tan 2B + \tan 2C = \tan 2A \cdot \tan 2B \cdot \tan 2C$$

Hence Proved.

- b.** Prove that, $\sin 10^\circ \cdot \sin 50^\circ \cdot \sin 60^\circ \cdot \sin 70^\circ = \frac{\sqrt{3}}{16}$

Ans. We have,

$$\begin{aligned} \text{LHS} &= \sin 10^\circ \cdot \sin 50^\circ \cdot \frac{\sqrt{3}}{2} \cdot \sin 70^\circ \\ &= \frac{\sqrt{3}}{2} \cdot \frac{1}{2} [2 \sin 50^\circ \cdot \sin 10^\circ] \sin 70^\circ \\ &= \frac{\sqrt{3}}{4} [\cos(50^\circ - 10^\circ) - \cos(50^\circ + 10^\circ)] \sin 70^\circ \\ &= \frac{\sqrt{3}}{4} \cdot \frac{1}{2} [2 \sin 70^\circ \cdot \cos 40^\circ - 2 \sin 70^\circ \cos 60^\circ] \\ &= \frac{\sqrt{3}}{8} \left[\sin(70^\circ + 40^\circ) + \sin(70^\circ - 40^\circ) - 2 \sin 70^\circ \cdot \frac{1}{2} \right] \\ &= \frac{\sqrt{3}}{8} [\sin 110^\circ + \sin 30^\circ - \sin 70^\circ] \\ &= \frac{\sqrt{3}}{8} \left[\sin(180^\circ - 70^\circ) + \frac{1}{2} - \sin 70^\circ \right] \\ &= \frac{\sqrt{3}}{8} \left[\sin 70^\circ + \frac{1}{2} - \sin 70^\circ \right] \\ &= \frac{\sqrt{3}}{8} \times \frac{1}{2} = \frac{\sqrt{3}}{16} = \text{RHS} \end{aligned}$$

Hence Proved

Q.8 a. Find the equation of the straight lines through the point (2,-1) and making an angle of 45° with the line $6x+5y-1=0$.

Ans. Equation of the straight line through (2,-1) and having slope m is
 $y + 1 = m(x + 2)$ _____(i)

(i) Makes an angle 45° with the line
 $6x + 5y - 1 = 0$ _____(ii)

Slope of (ii) is $-\frac{6}{5}$

$$\tan 45^\circ = \pm \frac{m + \frac{6}{5}}{1 - \frac{6m}{5}} \quad \text{or} \quad 1 = \pm \frac{5m + 6}{5 - 6m}$$

taking +ve sign,

$$5 - 6m = + (5m + 6) \Rightarrow m = -\frac{1}{11}$$

Taking -ve sign,

$$5 - 6m = - (5m + 6) \Rightarrow m = 11$$

Putting the values of m in (i) we get $y + 1 = -\frac{1}{11}(x - 2)$ and

$$y + 1 = 11(x - 2)$$

or $x + 11y + 9 = 0$ and $11x - y - 23 = 0$ are the required eqn. of the & line.

Ans. $x + 11y + 9$ & $11x - y - 23 = 0$

b. Find the equation of lines parallel to $3x - 4y - 5 = 0$ at a unit distance from it.

Ans. Equation of any line parallel to $3x - 4y - 5 = 0$ is $3x - 4y + k = 0$

Put $x = 0$ in $3x - 4y - 5 = 0$, we get $y = \frac{-5}{4}$

Therefore, $\left(0, \frac{-5}{4}\right)$ is a point on the line $3x-4y-5 = 0$ since the distance between the two lines is one unit therefore, the length of the perpendicular from $\left(0, \frac{-5}{4}\right)$ to $3x - 4y + k = 0$ is 1.

$$\text{Hence } \frac{3 \times 0 - 4 \times \frac{-5}{4} + k}{\sqrt{3^2 + (-4)^2}} = \pm 1$$

$$\frac{5+k}{5} = \pm 1 \Rightarrow 5+k=5 \text{ and } 5+k=-5$$

$$\Rightarrow k=0 \text{ and } k=-10$$

Putting the value of $k=0$ and $k=-10$ in (i)

$3x - 4y = 0$ and $3x - 4y - 10 = 0$ are the required equation of the straight lines.

$$\text{Ans } \begin{cases} 3x - 4y = 0 \\ 3x - 4y - 10 = 0 \end{cases}$$

Q.9 a. Find the equation of the circle which passes through the points $(3,-2), (-2,0)$ and having its centre on the line $2x - y - 3 = 0$

Ans. Let the equation of the circle be

$$x^2 + y^2 + 2gx + 2fy + c = 0 \text{ _____(i)}$$

as (i) passes through $(3, -2)$

$$\therefore 9 + 4 + 6g - 4f + c = 0$$

$$\text{or } 13 + 6g - 4f + c = 0$$

$$\text{or } 6g - 4f + c = -13 \text{ _____(ii)}$$

also (i) passes through $(-2, 0)$

$$\therefore 4 + 0 - 4g - 0 + c = 0$$

$$\text{or } 4g - c = 4 \text{ _____(iii)}$$

the centre $(-g, -f)$ of (i) lies on $2x - y = 3$

$$-2g + f = 3 \text{ _____(iv)}$$

adding (ii) and (iii), we get

$$10g - 4f = -9 \text{ _____ (v)}$$

Solving (iv) and (v), we get,

$$g = \frac{3}{2}, f = 6$$

Putting g in (iii), we get, $C = 2$

Substituting these values of g, f and c in (i) we get,

$$x^2 + y^2 + 3x + 12y + 2 = 0$$

which is the required equation of circle.

$$x^2 + y^2 + 3x + 12y + 2 = 0$$

b. Find the vertex, focus directrix, latus-rectum and axis of parabola

$$3x^2 + 12x - 8y = 0$$

Ans. The given equation is $3x^2 + 12x - 8y = 0$

$$3(x^2 + 4x - \frac{8}{3}y) = 0$$

$$\text{or } x^2 + 4x + 4 - 4 - \frac{8}{3}y = 0$$

$$\text{or } (x + 2)^2 = \frac{8}{3}y + 4$$

$$\text{or } (x + 2)^2 = \frac{8}{3}(y + \frac{3}{2}) \text{ _____ (i)}$$

Put $x + 2 = X$ and $y + \frac{3}{2} = Y$ (shifting the on origin)

$$\therefore \text{(i) reduces to } X^2 = \frac{8}{3}Y \text{ or } X^2 = 4\left(\frac{2}{3}\right)Y$$

Comparing with standard equation we get the following table:

Equation	$X^2 = \frac{8}{3} Y = 4\left(\frac{2}{3} Y\right)$	$(x + 2)^2 = \frac{8}{3}\left(y + \frac{3}{2}\right)$
Vertex	$(0, 0) \Rightarrow X = 0, Y = 0$	$\left(-2, \frac{3}{2}\right)$ [As $X = x + 2 \Rightarrow x = -2$ $Y = y + \frac{3}{2} \Rightarrow y = -\frac{3}{2}$]
Focus	$\left(0, \frac{2}{3}\right) \Rightarrow X = 0, Y = \frac{2}{3}$	$\left(-2, \frac{-5}{6}\right)$ [As $X = x + 2 \Rightarrow x = -2$ $Y = y + \frac{3}{2} = \frac{2}{3} \Rightarrow y = -\frac{5}{6}$]
Directrix	$Y + \frac{2}{3} = 0$	$Y + \frac{13}{6} = 0$ [As $y + \frac{3}{2} + \frac{2}{3} = 0$ $\Rightarrow y + \frac{13}{6} = 0$]
L.R.	$\frac{8}{3}$	$\frac{8}{3}$
Axis	$X = 0$	$x + 2 = 0$
